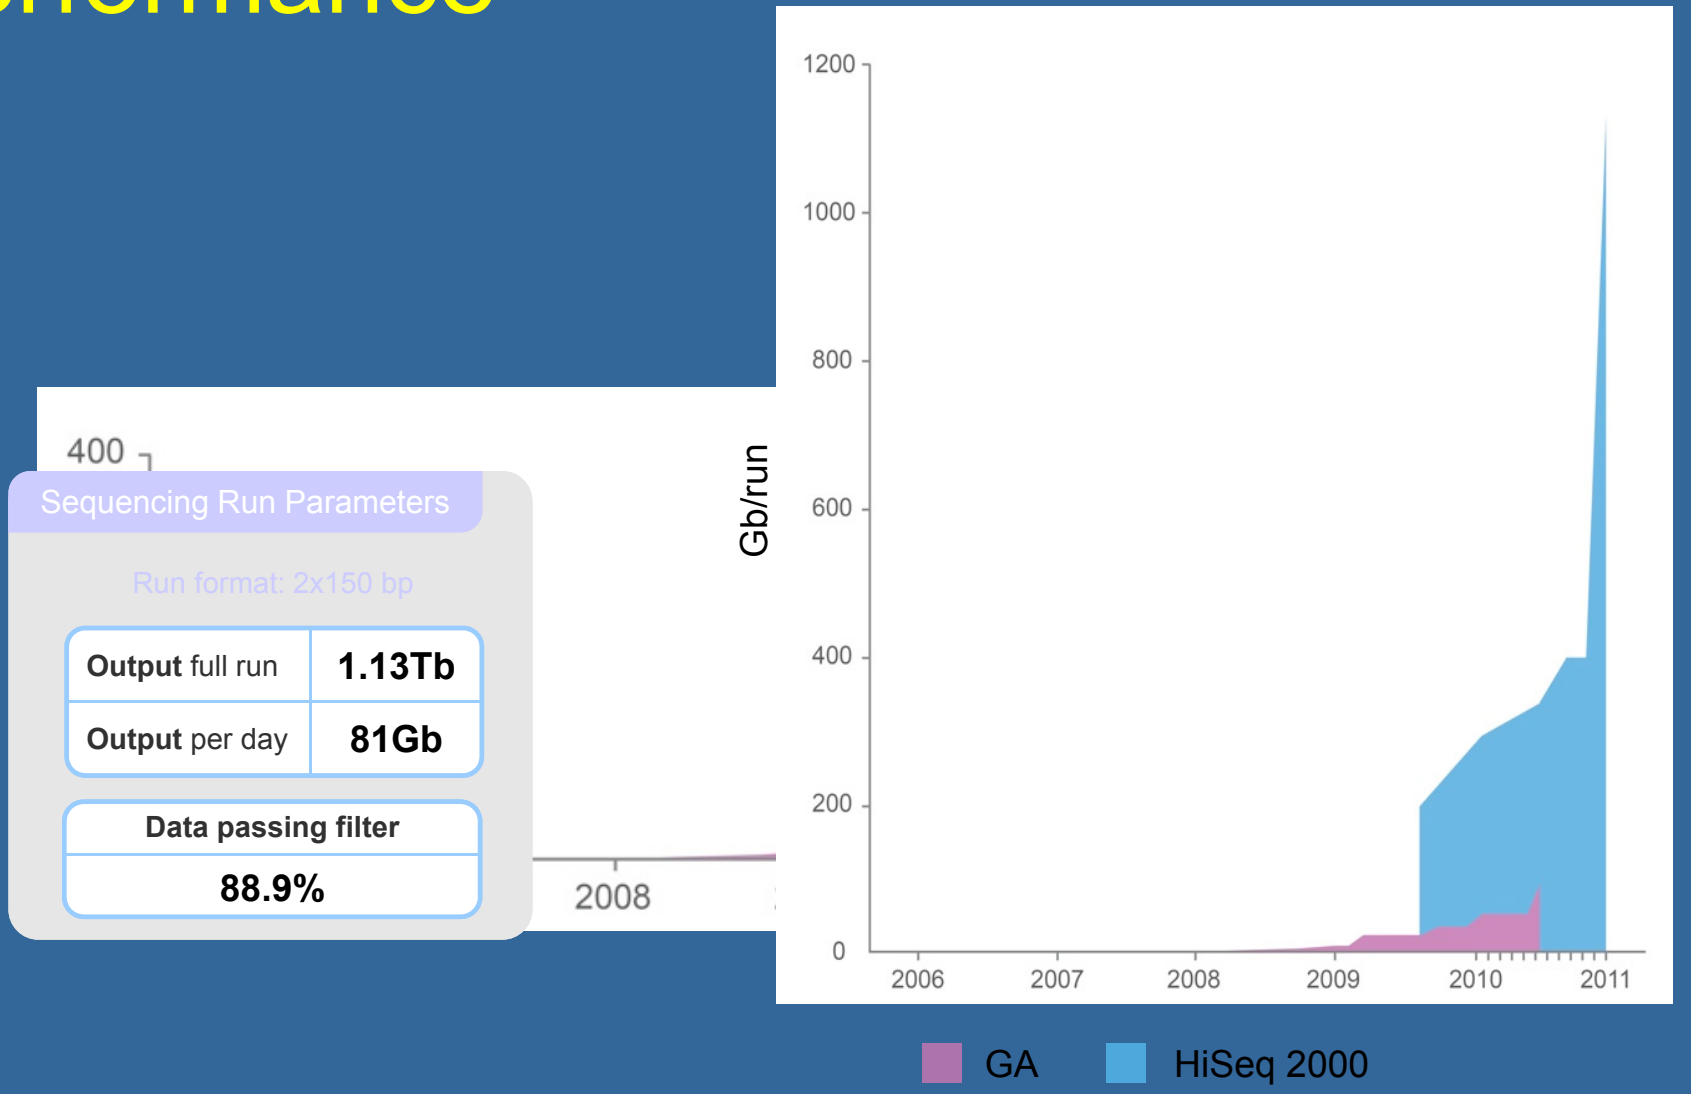
Integration of multiple datasets in head and neck cancer

Analysis of transcriptome and exome sequencing with methylation array data

David I Smith, Ph.D.
Professor
Chairman of the Technology Assessment Group
Center for Individualized Medicine
Mayo Clinic

HiSeq 2000

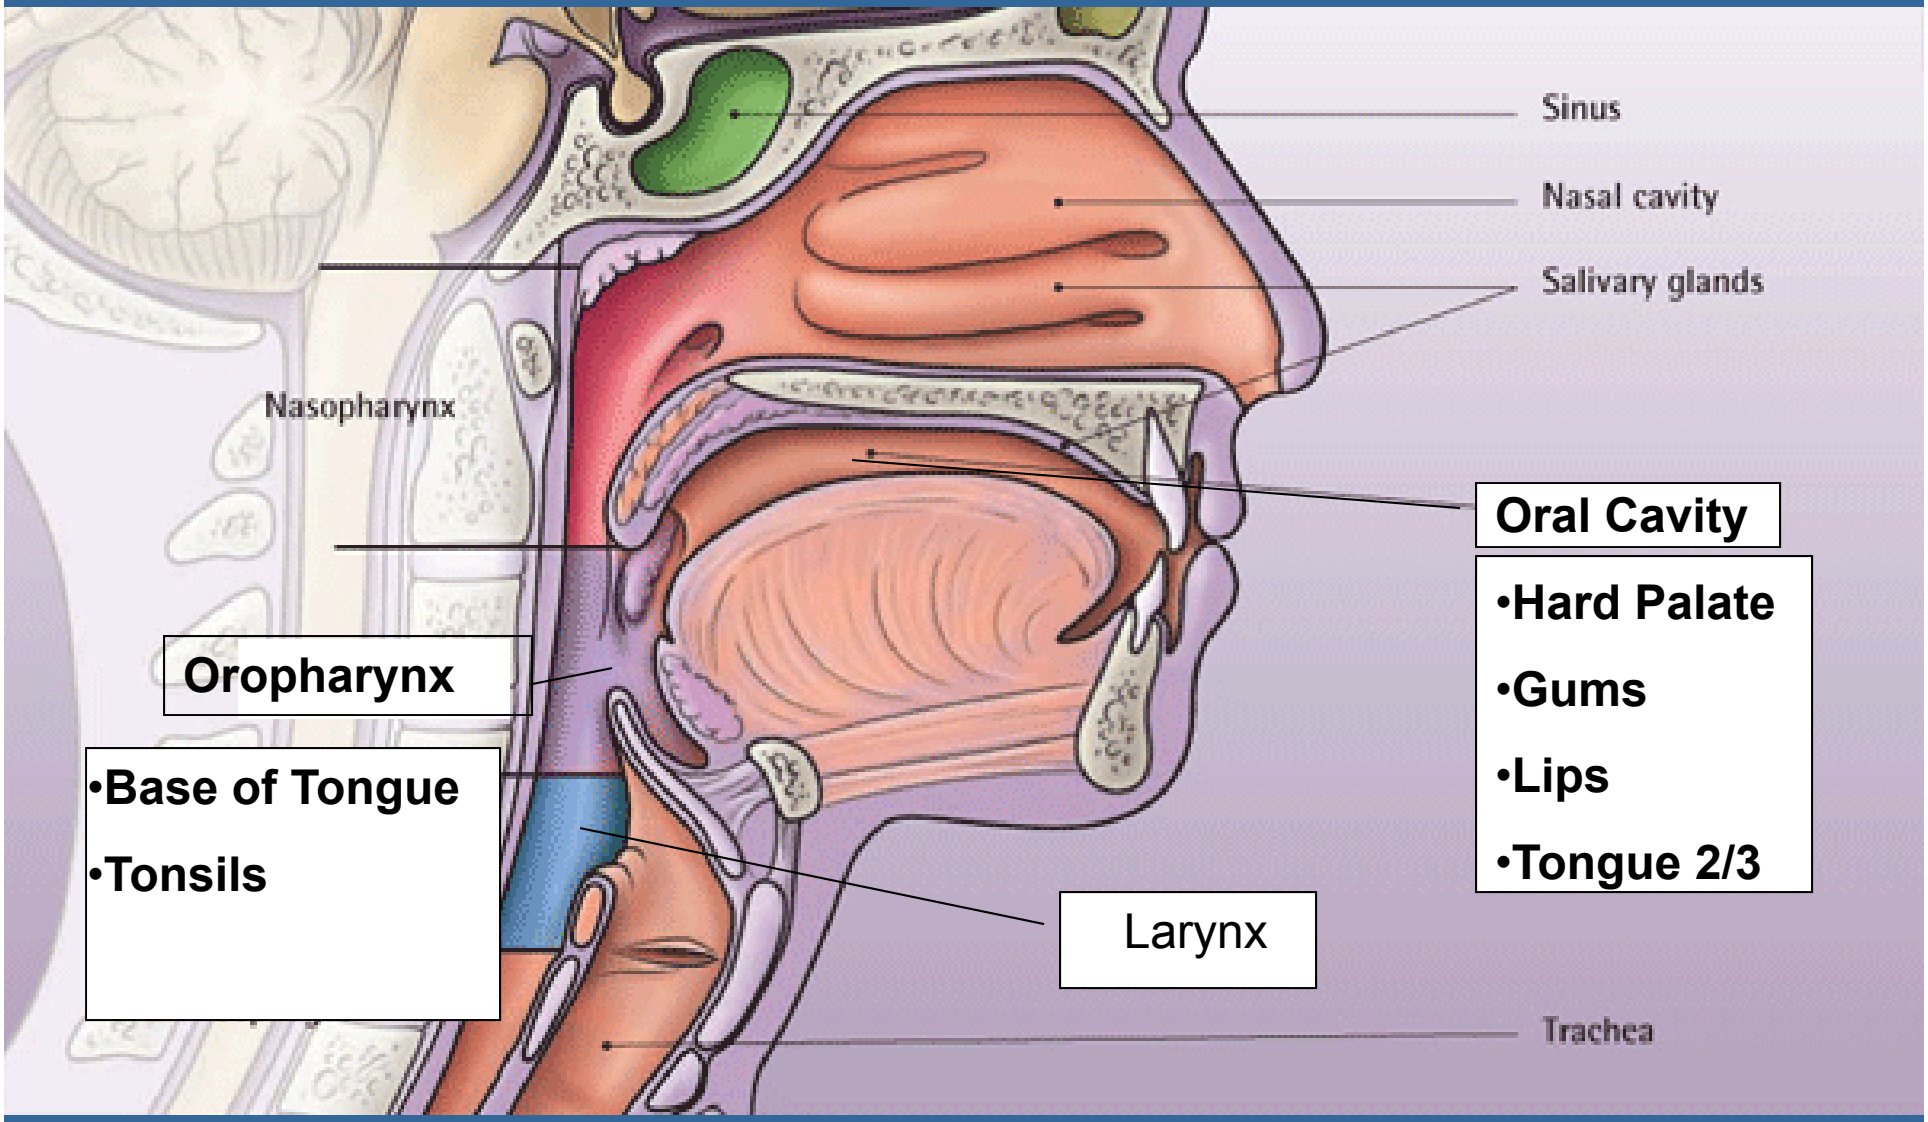
Evolution of Instrument Performance



Uses of Next Generation Sequencing

- Whole genome sequencing- requires 100+ gigabases of total sequencing (probably more for cancer genomes)
- Whole exome sequencing- requires enrichment of the exome and then deep sequencing of the resulting 50 Mbs
- Transcriptome sequencing- what is actively being transcribed in the cells of interest
- Methlyation sequencing- characterizing the epigenome, or utilize the Illumina 450K methylation arrays

Head and Neck Cancer



Head and Neck cancer

- 6th most common cancer
- Epithelial Cancers (Carcinomas)
  - Squamous Cell Carcinoma
  - Adenocarcinoma
  - Thyroid
- Mesenchymal
  - (Sarcomas)

Risk Factors

- Smoking and drinking
  - 6-7th decade of life, prolonged exposure
  - All sites

- HPV (16,18)
  - Oropharyngeal SCC (30-90% of patients)
  - Younger patients (<50 years)
  - Lack traditional risk factors
  - Chemo/Radiation Sensitive
  - Lacking strong evidence of consistent viral integration

Head and Neck Function

- Speech/Communication
- Swallowing
- Smell
- Taste
- Vision
- Cosmesis
- Hearing

Treatment

- Overall mortality ~ 60%
  - Depends on Patient, Tumor, and Treatment
- Treatment modalities
  - Surgery: Primary vs Salvage
  - Non operative therapy
    - Radiation: Primary vs adjunct vs salvage
    - Chemotherapy: adjunctive
      - Neoadjuvant (induction), adjuvant (concomitant)

Treatment modality

- Surgery: $30,000-50,000
- Radiation: $100,000-300,000
  - Outcomes roughly equivalent
- Chemotherapy: $100,000-500,000
  - 4% survival benefit in select patients
  - 4% of patients die from treatment
  - Financial incentive to treat with Radiation/Chemo?

HPV not just in the cervix/cervical cancer

- In cervical cancer HPV long-term infection coupled with eventual integration appears to be the trigger causing cervical cancer
- HPV also found in some head and neck cancers, anal cancer, vulva and vaginal cancer, and cancer of the penis
- Role of HPV in these other sites is less well understood, however

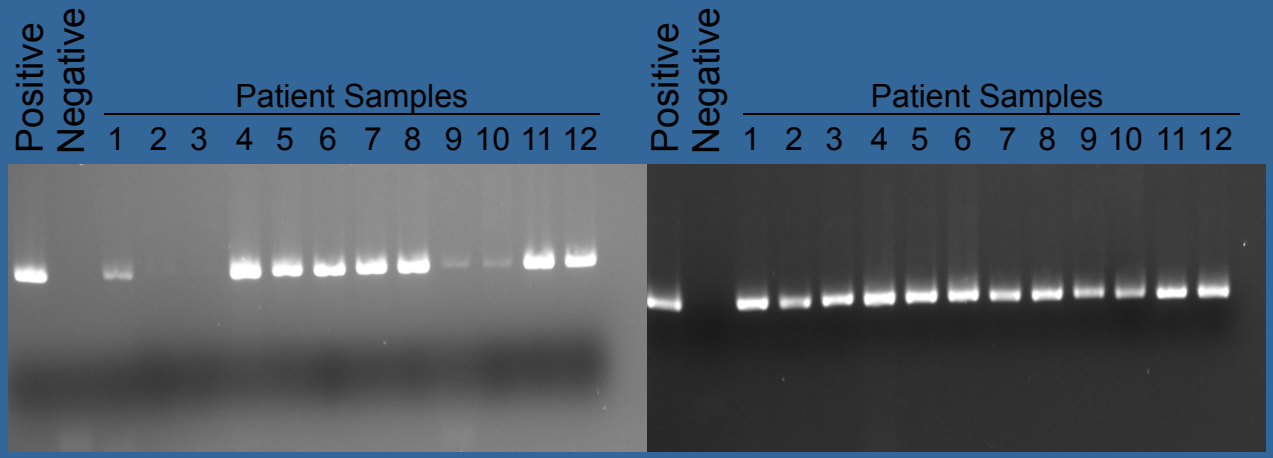
HPV oncogenes

- E6 and E7 genes are consistently expressed in HPV infected cells
- HPV E6 decreases p53 expression
- HPV E7 gene leads to loss of pRB cell cycle arrest
- pRb negatively feeds back on p16
- When pRb is down regulated by HPV E7, p16 is over expressed

Detecting HPV in head and neck cancer

- In situ hybridization for HPV sequences
- PCR for HPV DNA
- Immunohistochemistry for p16 expression (which is elevated in HPV+ cancers)
- Detection of transcriptionally active infections by measuring RNA transcripts, or protein for the oncoproteins E6 and E7

HPV Detection by PCR



Universal Primers **HPV 16 Specific Primers**

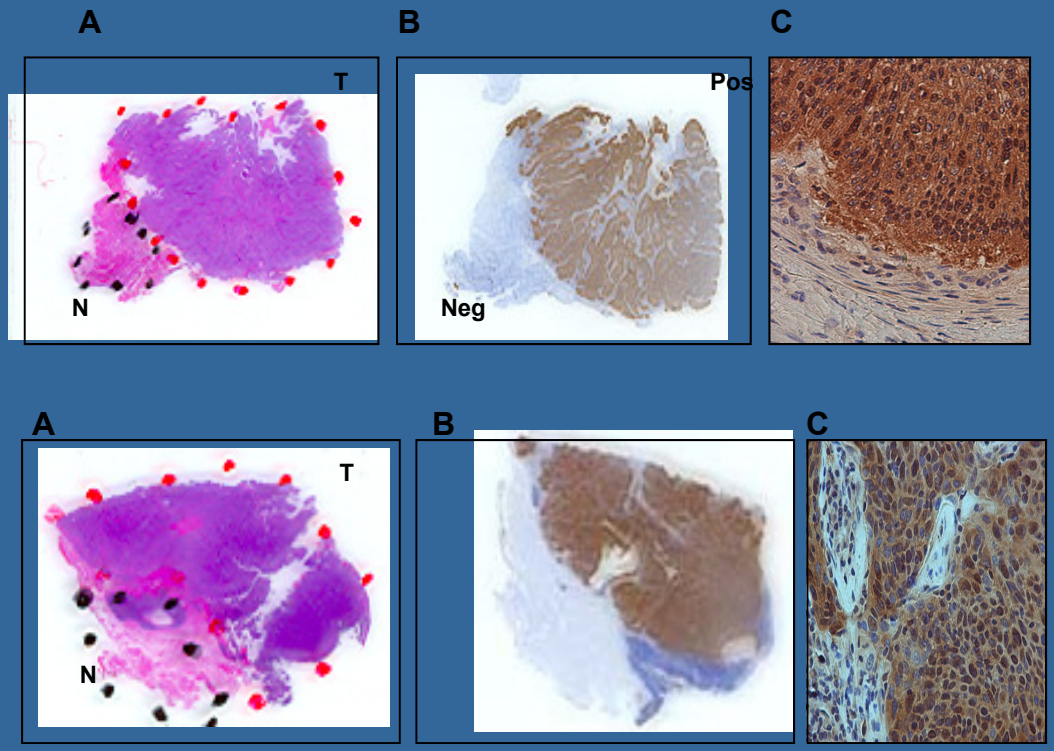
- More Consistent results from Fresh Frozen Tissues versus Paraffin Embedded Samples

HPV Detection by IHC

A: H&E Stain

B: IHC p16^{INK4A}

C: IHC p16INK4A (40X)



HPV E6 and E7 Expression by Q-RT PCR

- Not routinely done
- Difficulty in doing this out of paraffin
- New technologies to do this- Nanostring, Fluidigm, or Advanced Cell Diagnostics (RNAscope)

HPV Infection Rates

- High rates of HPV positivity in BTT (oropharyngeal) tumors (26-91%), Is this because HPV rates differ in different populations or is this a technical problem?
- Low rates of HPV positivity in Oral Cavity tumors (3-11%)

- Oropharyngeal HPV+
  - HPV16,18 most common, other sub-types?

Two distinct entities of oropharyngeal cancer?

- HPV minus – generally older smokers and drinkers. Much worse clinical outcome due to more DNA damage
- HPV positive- contains those individuals who are both younger and many are non-drinkers/non-smokers. Less DNA damage, hence possibly more treatable?
- Not clean groupings as there are smokers/drinkers that are also HPV positive

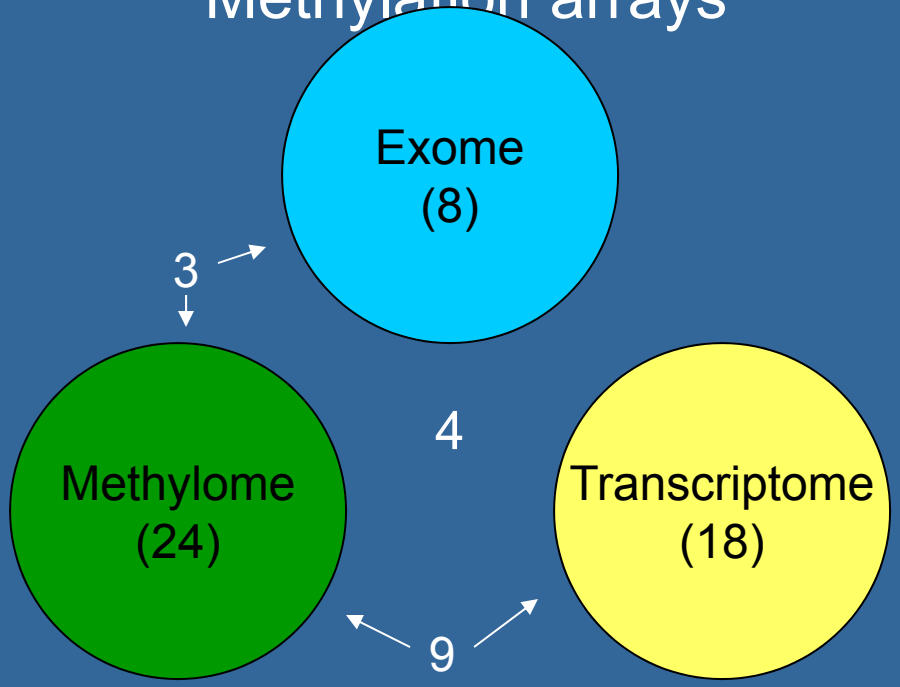
Which factors are most significant for the development of disease?

Application of Massively Parallel DNA sequencing and related technologies

mRNA-Seq / nCounter (or other) validation

Exome sequencing

Methylation arrays



Application of Massively Parallel DNA sequencing and related technologies

mRNA-Seq / nCounter validation

Exome sequencing

Methylation arrays

Clinical Application - Tool Development

Patient knowledge of technologies - expectations

Discovery - Experimental

Clinical Applications

- Supplement current technologies for diagnosis (detection of HPV)
- Develop markers for patient stratification based on most significant risk factors
- Develop tools for early detection of primary disease and recurrence

Experimental Interests

- Transcript dysregulation
  - Risk factors, sites, disease behavior
- Non-coding transcripts
- Fusion transcripts
- Methylation and mutations – define mechanisms of genome dysregulation

mRNA-Seq Transcriptional profiling of Oropharyngeal SCC

- 18 Tumor and Patient Matched Normal Tissue Samples
- Illumina GAIIx (12 samples) (oligo dT-primed) and SOLiD (6 samples) (Ribominus removal of rRNA species)
- ~65 million reads per sample (200 million for SOLiD RNAseq)
- Data analysis –
  - Genesifter, Geospiza, Seattle WA

RNAseq on T/N Pairs

- Illumina GA IIx or SOLiD 4

	Age	Gender	Illumina/SOLiD
Current Smoking	56	M	Illumina
	73	M	Illumina
	54	M	Illumina

	48	M	SOLiD
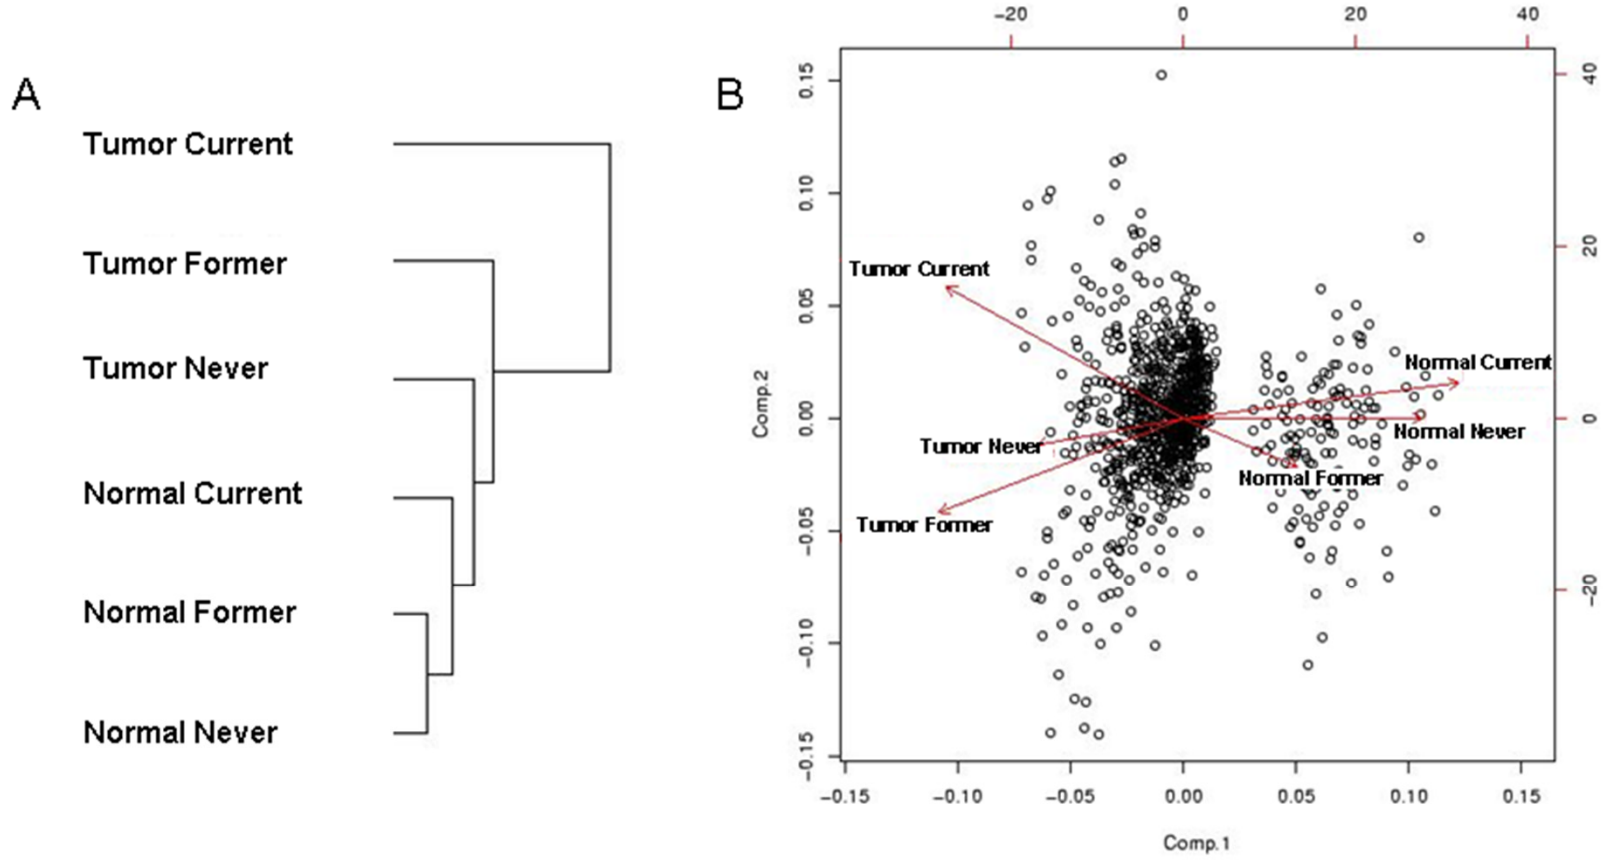
	55	M	SOLiD
	54	F	SOLiD

Develop markers for patient stratification based on most significant risk factors

- Patients present with overlapping risk factors
- Patient self-reporting of tobacco exposure is often unreliable
- Lack of mechanism for role of HPV

Global Gene Expression mRNA-Seq

patients grouped by smoking status

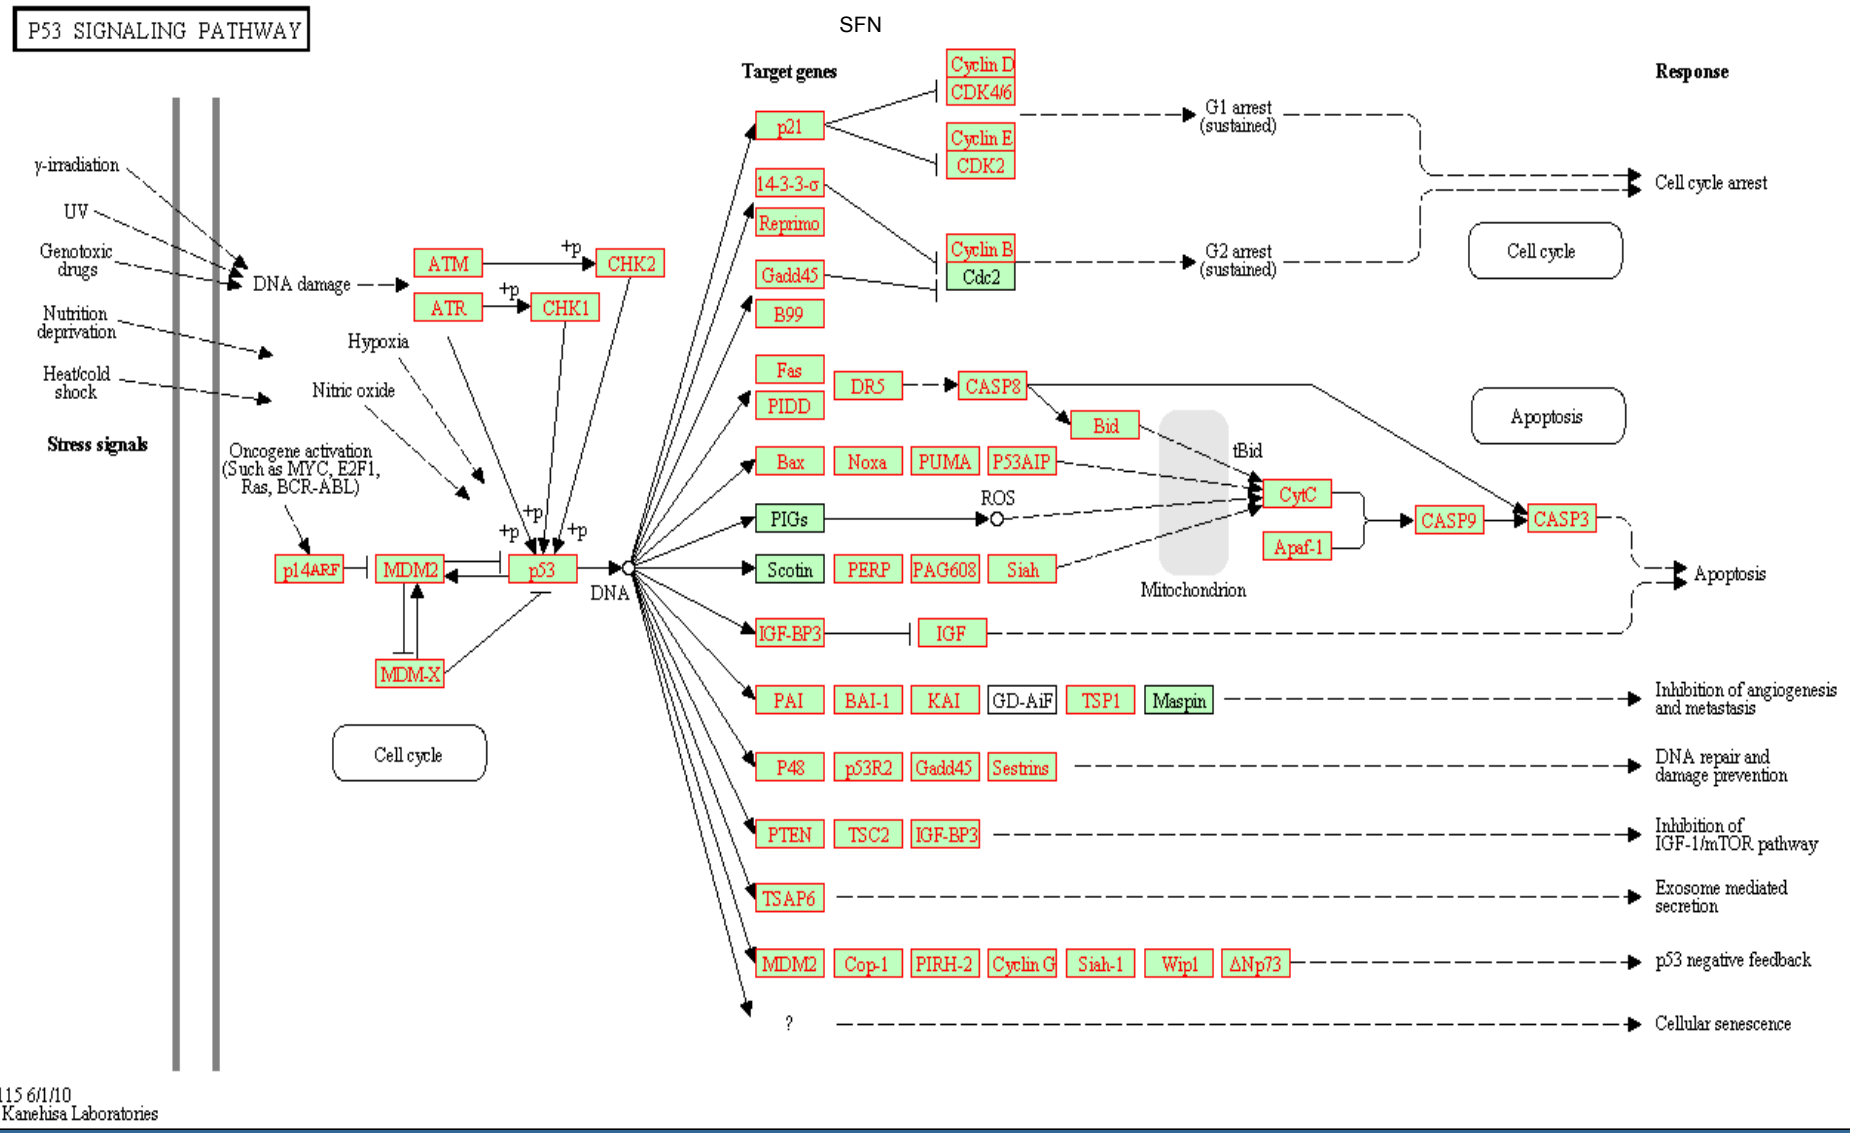


Analysis of transcriptional profiling

- Differentially regulated genes
  - HOX, MMPs, T cell signaling, Immune responsive gene targets
- Pathway analysis (Genesifter)
  - p53 signaling pathway
  - Is there a difference between groups divided by risk factor

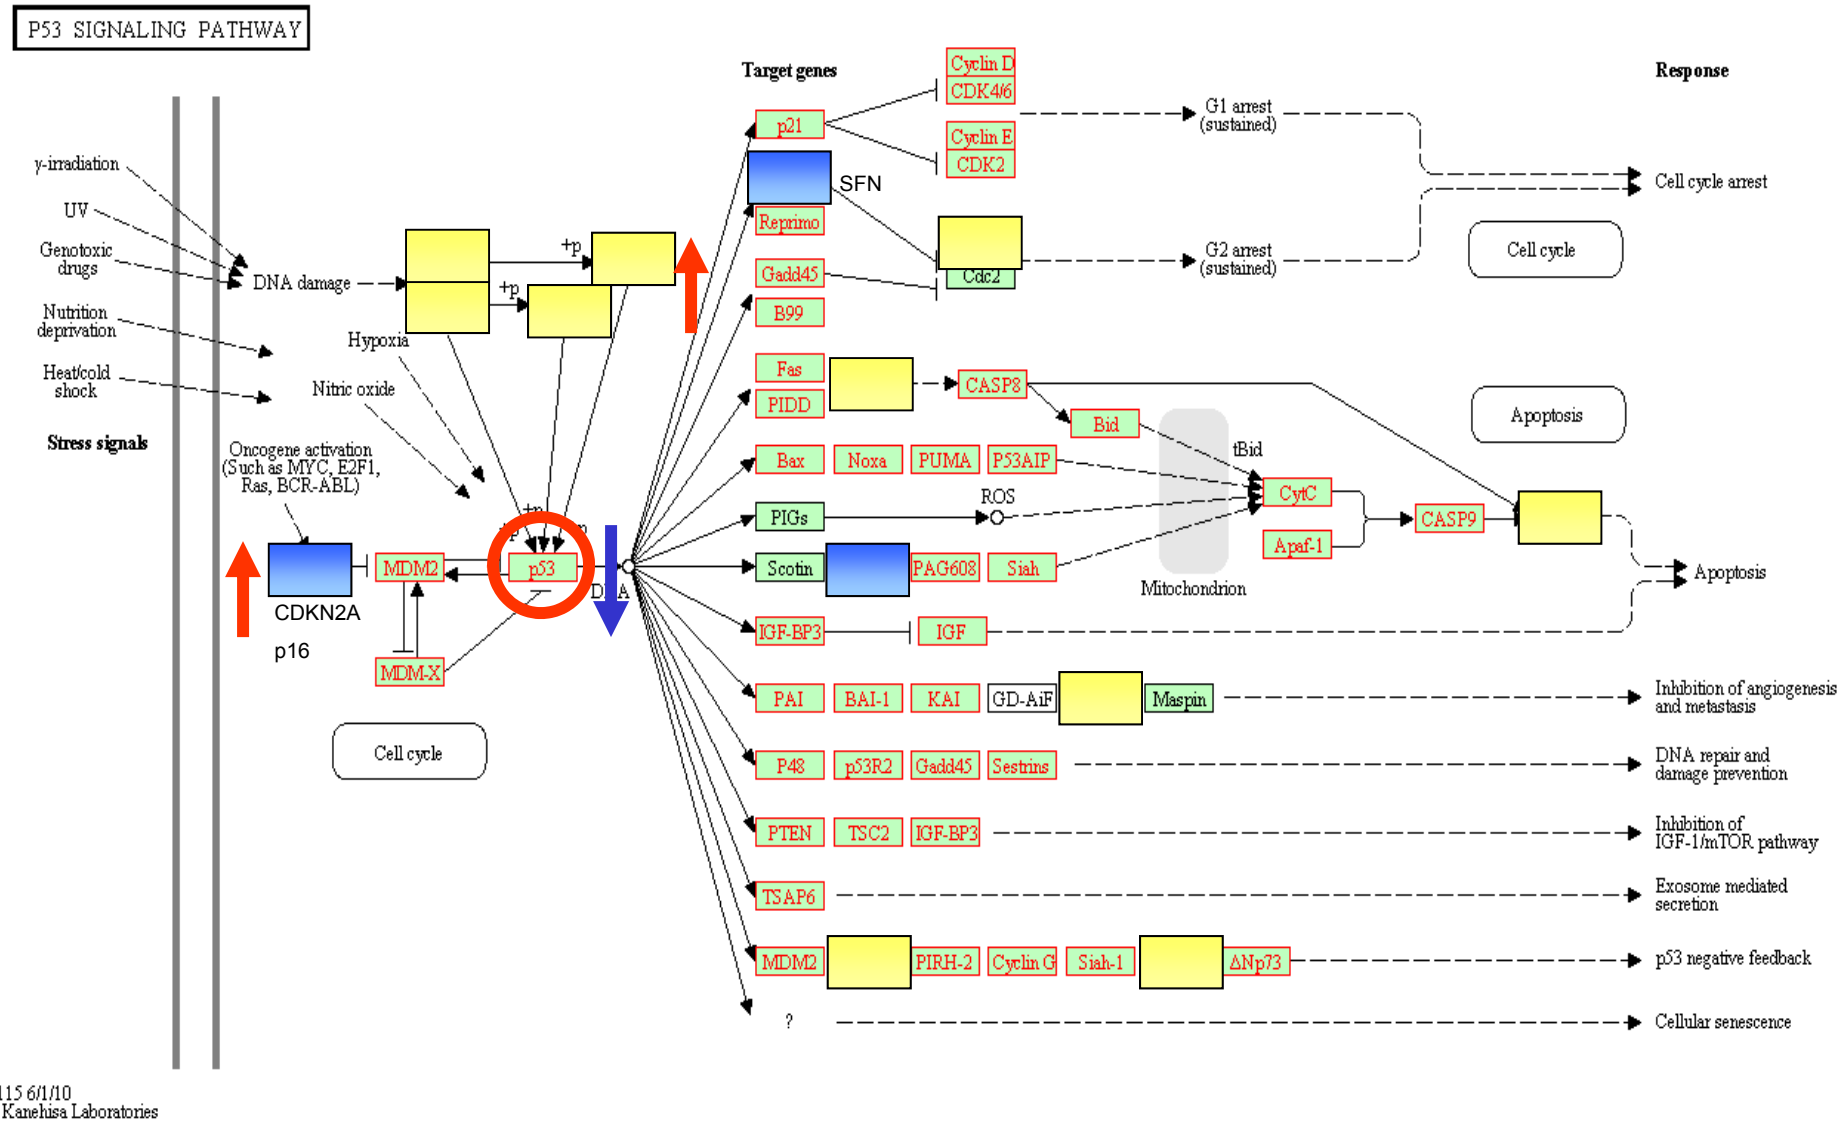
Regulatory Non-coding Transcripts

Transcriptome Analysis : Differential T/N

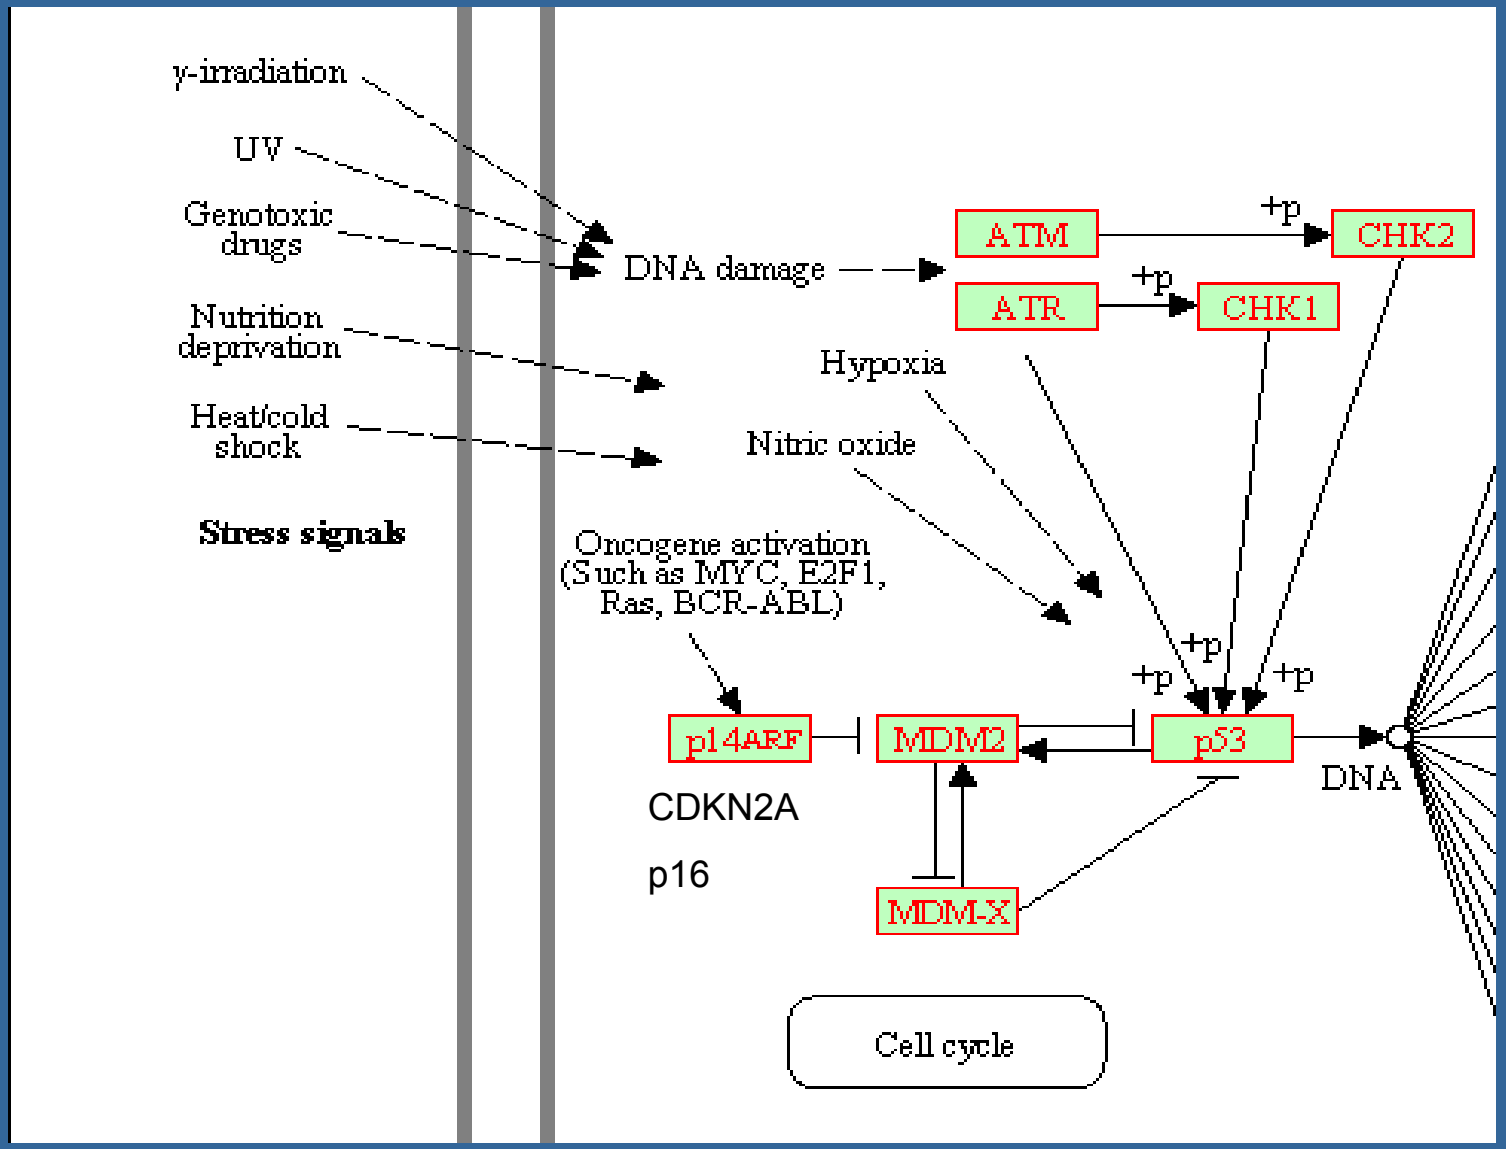


Current Smokers

Never smokers



p53 Signaling



Validation Experiments

- Small sample size restricts analysis
- Validate in larger number of tumor/normal pairs
- Nanostring nCounter digital counter
  - 96 gene codesets
  - 44 sample pairs
  - 100ng input RNA
  - Compare fresh frozen to FFPE

nCounter Codesets

What else is altered in cancer?

- Genome wide changes in methlylation
- Methylation changes may be a better direct indicator of environmental exposures
- How to measure methylation? Whole genome sequencing before and after bisulfite modification is one expensive way
- Alternative is a $450 array that measures 450,000 methylation sites in the genome. Downside- only a small fraction of all methylation sites

Methylation Array

- Infinium Human Methylation450 BeadChip Kits

Background

- Methylation: addition of methyl group to a substrate or the substitution of an atom or group by a methyl group.
- DNA methylation at CpG sites
  - conversion of the cytosine to 5-methylcytosine
  - Methylation in promoter region: Inverse relationship with transcriptional activity

Methylome

- Identify differentially methylated cg sites
  - SAM:
    - We chose a delta with which the median FDR among all cg sites is 0.01.
  - Limma:
    - Adjusted P-value < 0.01.
- Overlap of limma result and SAM result: 11,383 cg sites. 49,047 are hyper-methylated, 64,806 are hypo-methylated.

Similar patterns of variability when comparing transcriptome analysis and hypermethylation of current smoking patients

Correlation Between Two Datasets

- 7 patients have both methylome and transcriptome data.

- Spearman correlation:
  - 14 pairs of M-value and expression value
  - cg site and the gene it lies on
  - Hyper-methylation with down-regulation; hypo-methylation with up-regulation.

Two Lists of Genes Chosen

- Genes that are differentially methylated when comparing tumor to normal and have corresponding expression change
- Genes that are differentially methylated when comparing the smokers to the non-smokers and ex-smokers

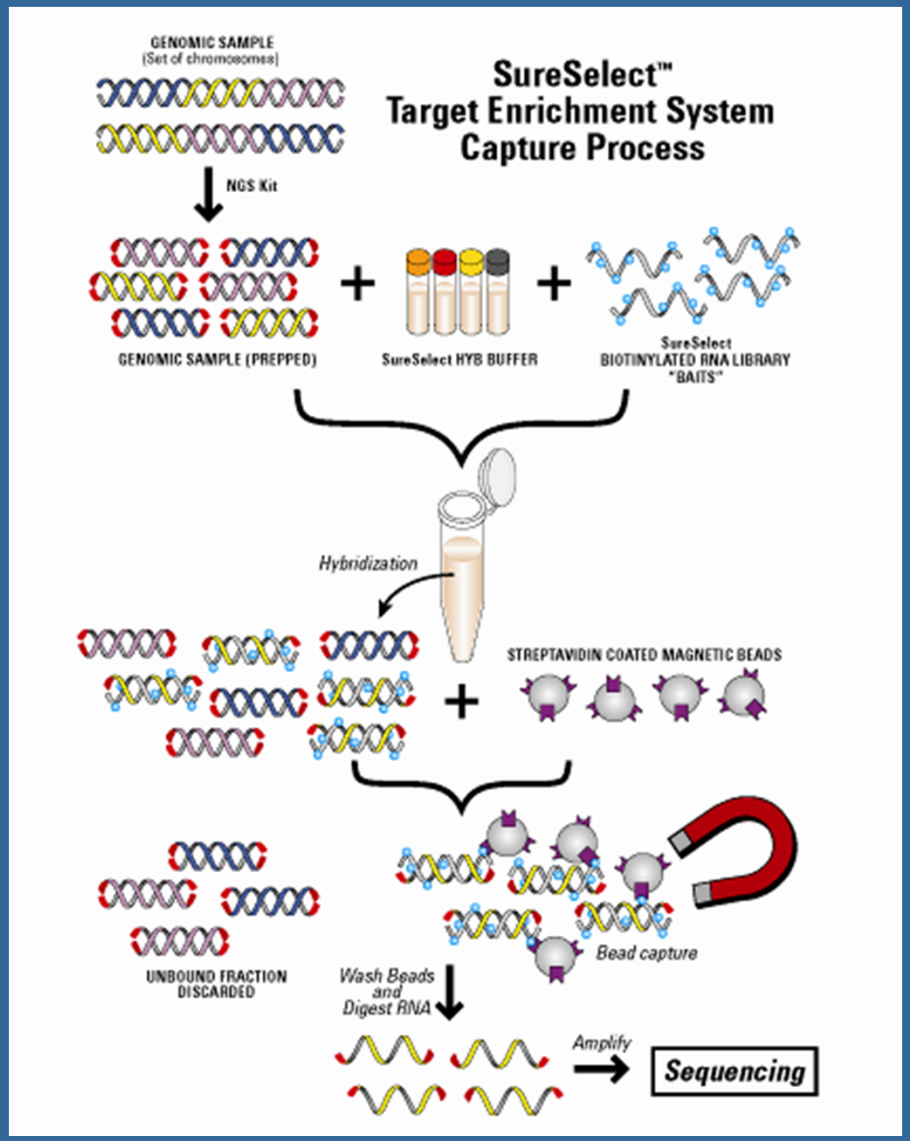
Validation

- Limited resources (both financial and in terms of tissue material)
- Fluidigm- Nanofluidics solution that can measure expression of 96 genes (or 48 in duplicate) against 96 samples
- Requires 5 nl per individual reaction
- Both cost and tissue effective- but you still need to purchase TaqMan probes for each gene

Whole Exome Sequencing

- Instead of sequencing the entire 6 Gb genome, why not “pull down” the 38 Mb exome?
- Much less sequencing and can sequence the exome at depth (100+ coverage)

SureSelect™ Target Enrichment System: Workflow



Agilent Technologies
SureSelect™

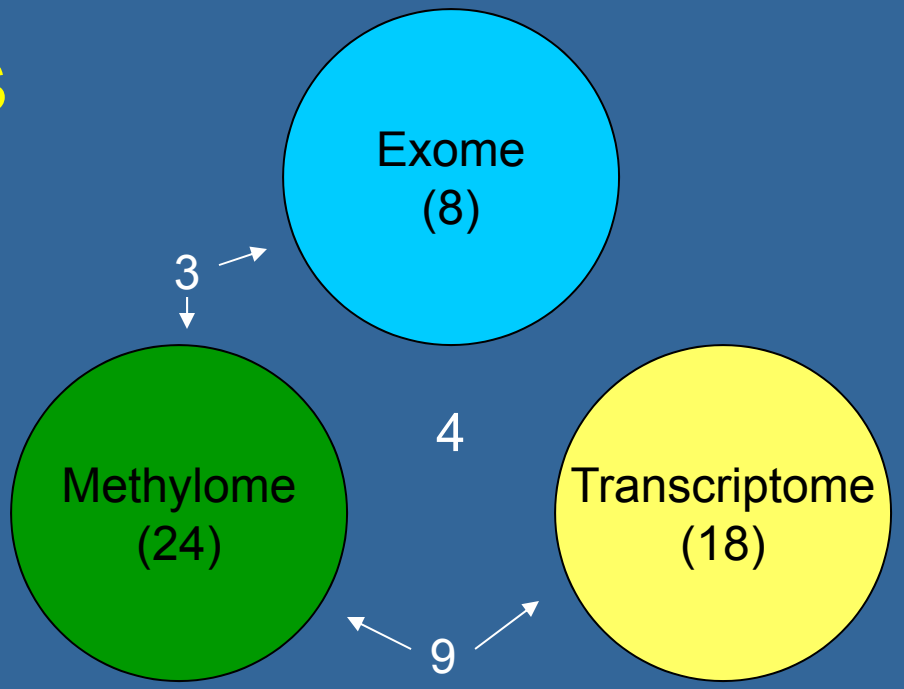
PRAME

Integrating datasets



- Correlate patterns of differential expression to
  - DNA Mutations
  - Differential Methylation
- Validate exome mutations in transcriptome
- Identify RNA editing events
- Correlate methylation patterns with differential splicing events

Moving forward

- Identify gene expression patterns of key pathways that associate with risk factor groups
  - In an individual patient, which risk factors are most significantly influencing disease development
- Compare multiple datasets to determine mechanism
  - Exome sequencing (mutations)
  - Methylation Arrays
  - Biological marker of tobacco exposure

General Conclusions

- Sequencing tools have important potential for clinical application
- Importance of building larger datasets
  - Correlate with disease outcome as they mature
- Importance of integrating datasets
    - Correlate with exposure, etiology, response to therapy
- Bottleneck involves bioinformatic challenges
