Introduction

The Flow Cytometry Research Group (FCRG) is the latest addition to the ABRF RG family. This RG is currently in its first year and has 10 members, several of whom are new to the ABRF but have been very active in and come from the flow cytometry core community. The FCRG has submitted a 3 year research plan that will characterize alterations in both gene expression and ultimately cellular function as a result of the stresses imparted by cell sorting. We will use a variety of cell types, lasers, and sorters to identify optimal conditions and eventually Best Practices for minimal cellular system disruptions. Integration of flow cytometry with other core technologies and ABRF RGs will become even more critical as many new technologies will fully take advantage of the sample processing capability of cell sorting allowing higher resolution targeted downstream molecular applications such as single cell gene expression. The new FCRG will seek to foster collaboration, integration and synergy between experts of diverse technologies the very factors that will become increasingly vital to successful research.

Methods

Beckman

Coulter

Quanta SC

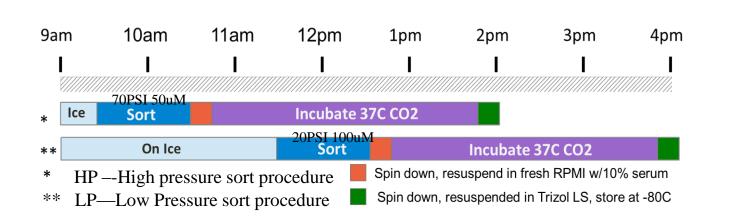

An and a second second

• Jurkat cell line cultured to log phase 95% viable by PI and Trypan blue. Size concentration, and uniformity confirmed on Quanta SC (Beckman Coulter) cytometer. Sorter sterility was assessed by standard microbiological methods.

- Post-sort viability assessed with Celigo-- Bright field, Hoechst, and PI fluorescence image analysis.
- Immediately before each sort condition, an aliquot from Master Stock was filtered through 30µm mesh. Unsorted control samples, were adjusted to simulate the media condition of sorted samples.
- Sort and control samples were kept at room temp (RT) for the duration of the specific sort.
- Prior to sort, Master Cell Stock was kept on ice:
- » High Pressure sort performed early in the day-- 30 min on ice » Low pressure sort performed 3 hrs later- -----210 min on ice
- Following sort cells–both sorted and unsorted control-were pelleted by centrifugation, re-suspended in fresh growth media, cultured at 37° C. 3 hrs before harvested for RNA
- Cell pellets were homogenized in Trizol LS and stored at -80° C.
- RNA was isolated from Trizol, processed with RNeasy Mini Column system (Oiagen) and quantified using Nanodrop ND1000, followed by assessment on the Agilent 2100 Bioanalyzer.

RNA Processing and Data Analysis

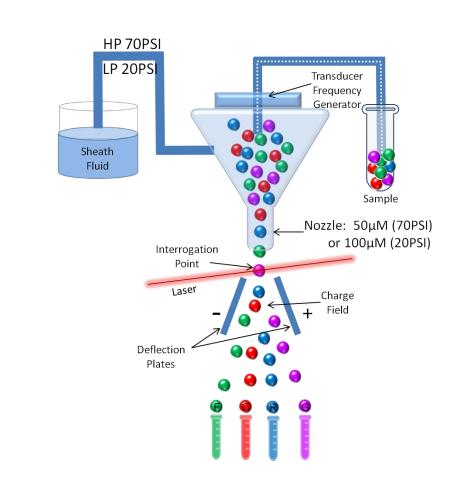

RNA was converted to labeled cDNA, fragmented and, hybridized to the GeneChip Human Gene 2.0 ST arrays using the standard WT protocol from Affymetrix. Resulting CEL files were exported to GeneSpring GXv12.5, quantile normalized using Plier16 and baseline transformed to the median of all samples. The entity list was then filtered to remove those with signal in the bottom 20th percentile across all samples and further refined to exclude entities >25% CV across all replicates in a condition. This target set was interrogated for entities with >1.5 fold differential expression and statistical significance (p<0.05, Benjamini Hochberg FDR corrected) between the conditions being compared.

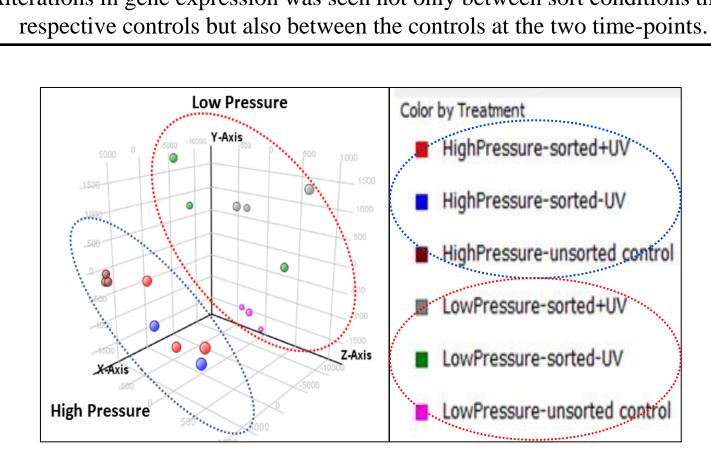

A single Master Stock of cultured cells was harvested, pooled and stored on ice prior to sort. One aliquot was taken from the Master Stock for HP sort. The remaining Master Stock remained on ice until an aliquot was taken for the HP sort –LP ice time 30 min., --HP 120 min. Sort performed at ~25°C (RT). Each sort condition embedded 3 replicate processes. Control (unsorted) cells were removed from ice with the sort aliquot, held at RT during the sort, then processed parallel to sorted sample (spin/Trizol).

How Does Cell Sorting Work?

- The stream is separated into droplets.
- point

- molecular analysis.
- Highly pure subsets are routinely used in static gene and protein analysis. This purity reduces interfering signals (noise) from irrelevant cell populations that confound the exquisitely sensitive bio-analytic tools available to researchers today.
- Small nozzle sizes and high system pressure alone may be traumatic to cells. Rapid depressurization at the nozzle tip could destabilize a cell.
- The small nozzle/high pressure used in the extreme condition for this study would not typically be employed to harvest live cells. • Live sorts of Non-hematopoietic cells usually employs 100, 120 or 150µM nozzles at 20, 15
- or 12 PSI respectively.

3D Gene Expression principle component plot of flow sorted Jurkat cells following 3 hr postsort incubation in complete RPMI growth media. Jurkat cells were sorted at either high (70PSI/50µM nozzle) or low (20PSI/100µM nozzle) pressure settings. Both pressure/nozzle conditions included either shielding or exposure to UV laser-a hypothesized trigger of differential expression. Data clearly indicate differential gene expression for sorted cell populations regardless of pressure compared to their respective unsorted control. Additionally, even more striking differences are seen between the 2 unsorted controls, indicating an underappreciated effect of the duration of cell storage on ice while waiting to be sorted.

H Pletcher⁹, S Tighe¹⁰

FACS—Fluorescent Activated Cell Sorting enables purification of very specific cell subsets

• Droplets containing the target cells are electrically charged below the interrogation

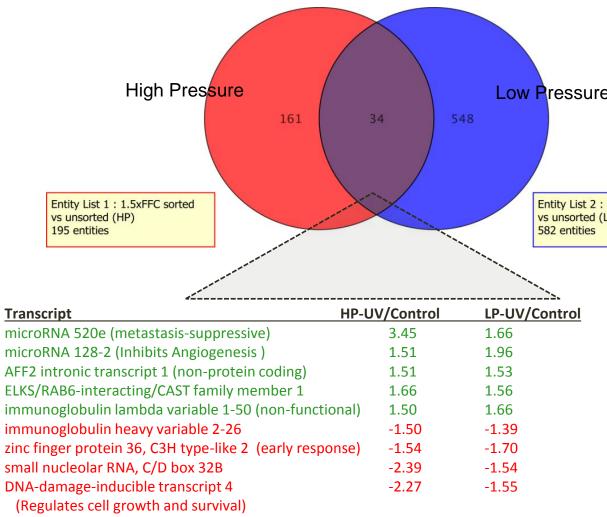

• Charged plates deflect the differentially charged droplets into a tube.

Functional or Static analysis– cells can be live, functional and pure or can feed directly into

Results

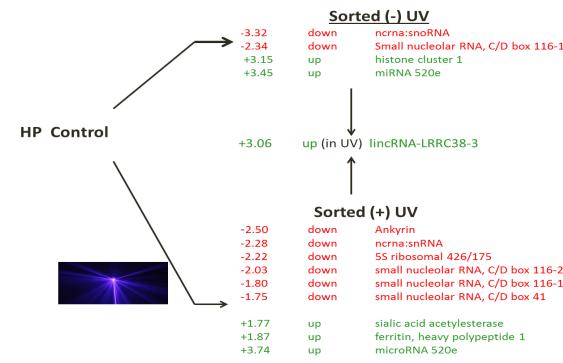

Alterations in gene expression was seen not only between sort conditions their
